Reproductive Allocation In Plants Physiological

Reproductive Allocation in Plants describes why plants differ in the proportion of their resources that they allocate to reproduction and looks into the various theories. This book examines the ecological and evolutionary explanations for variation in plant reproductive allocation from the perspective of the underlying physiological mechanisms controlling reproduction and growth.

Plants, like other organisms, have a limited lifespan and limited resources to allocate during the time in which they grow and reproduce. Because plants are usually sessile and often very plastic in their growth and reproductive habits, they were ideal for studying variation in reproductive allocation during the formative years of research.

The trade-off between allocation to reproductive or vegetative growth in response to elevation gradients is a strategy used by plants in response to increased inundation in wetland habitats (Xiao et al., 2011; Chen et al., 2015).

In gender dimorphic species, reproductive allocation (RA, the ratio of reproductive to vegetative biomass) is predicted to be greater in female plants than in male plants. Empirical research on dimorphic plant species supports this hypothesis.

Reproductive Allocation In Plants Physiological Ecology [EPUB]

The physiological cost of reproduction was investigated in a perennial plant species, *Sidalcea oregana* ssp. *spicata*. Two different classes of estimates of current reproductive investment were compared, with the goal of identifying the most powerful predictor of future reproductive effort. "Static" estimates, those typically used to measure current reproductive investment (i.e., biomass or ...

Similarly, plants also tended to reduce the reproductive investment (Figure 1) that requires vast amounts of energy and water (Karlsson & Méndez, 2005), because reduction in photosynthesis (Su et al., 2013) and changes in phenology (e.g., shortening growth period and early flowering) in relation to drought cause significant reduction in biomass allocation to reproductive parts (Farooq, Wahid ...

Reproductive allocation was measured in 2000 on the 20 plants at Tidbinbilla and in 2002 on all sample plants at the three sites. We estimated RA using reproductive biomass, including peduncles, flowers and fruits, as a proportion of vegetative biomass (Reekie & Bazzaz 1987a ; Obeso 2002).

Reproductive allocation in a gender dimorphic shrub ...

Suppression of reproductive allocation resulted in a direct reduction in somatic costs of reproduction, expressed through changes in growth variables and plant physiological status. Inflorescence bud removal was related to an increase in shoot elongation and water potential in male and female plants.
